17
18 **Abstract:** In this study, the Henry's Law Constant and the activity coefficients in infinite
19 dilution in a mass fraction of 25%, and 50% of methyldiethanolamine (MDEA) aqueous
20 solution within the temperature range of 298-348 K at atmospheric pressure, were measured.
21 An inert gas stripping method was used to perform all the measurements. The new values of
22 Henry's Law Constant and the activity coefficients in infinite dilution correlation with solute
23 molecular size were explained. The influence of the solvent is discussed taking into

1 consideration the heat of absorptions for different MDEA concentrations. Experimental
2 results are compared to literature data wherever available.

3

4 **Keywords:** solubility, limiting activity coefficient, heat of solution

1. Introduction

Raw natural gas produced from gas fields always contains contaminants or other unacceptable substances including carbon dioxide, hydrogen sulfide, water, carbonyl sulfide, mercaptans (thiols), heavy hydrocarbons and mercury [1]. Removals of these contaminants are achieved through the acid gas treating/sweetening or gas purification process before it can be marketable. Currently, aqueous alkanolamine systems (amine systems) have been used extensively for the removal of acid gases from gas mixtures and it is considered as the most established technology [2-4]. The use of methyldiethanolamine (MDEA) for sour gas treatment is preferred due to its high equilibrium loading capacity and low heat of reaction with CO₂, hence lowering the energy requirement for regeneration [5-6].

Mercaptans are one of the contaminants found in sour gas which has to be removed in view of its toxicity which was reported to be similar to hydrogen sulfide [4]. In the context of growing concern on environmental issues, regulatory limits on gas emissions have been progressively reduced in line with the global trend towards more stringent specifications on gas impurities emissions from natural gas processing facilities. Huguet et al. [7] reported the specification of typical treated gas containing minor amounts of contaminants is as low as 2% CO₂, 2–4 ppm H₂S and 5–30 ppm total sulfur (mercaptans and COS). Furthermore, any mercaptans that are not absorbed from sour gas through the amine purification units complicate the process scheme for downstream liquid treatment units [8].

In response the trend, gas preconditioning upstream, or final step(s) for gas conditioning downstream of the gas-treating unit, are increasingly being considered as the better options to comply with the more stringent regulations [9]. Hence the study of solubility of sulfur components (in this study, mercaptans is considered) in amine systems will undoubtedly become increasingly important for the process designers and operators in order to conform to

1 the regulatory limits. According to Pellegrini, et al. [10], and Langè et al.[11], these
2 restrictions have also led engineering companies to investigate the effects of these substances
3 on the performances of amine systems.

4 Therefore it is crucial to understand the thermodynamic behaviour of mercaptans in amine
5 solutions which will enable for selection to be made for the best solvent. This can be realized
6 by considering the limiting activity coefficient (or Henry's law constant) and the activity
7 coefficient at infinite dilution for mercaptans in amine solutions. These thermodynamic
8 quantities served as important parameters for the design of separation process. Krummen et al
9 [12] mentioned in his work that the separation of the final traces of components requires
10 significant effort as the region within infinite dilution gives the least favourable values of the
11 separation factor.

12 This work is the continuation of the previous works [13,14] in which we have determined
13 the limiting activity coefficient of n-propylmercaptan, n-butyl mercaptan and dimethylsulfide
14 in pure water and in 25 and 50 wt% concentration of methyldiethanolamine (MDEA) aqueous
15 solution. The study focuses on the measurement of the Henry's law constant and the infinite
16 dilution activity coefficient of isopropyl mercaptan and isobutyl mercaptan in a mass fraction
17 of 25%, and 50% concentration in methyldiethanolamine (MDEA) aqueous solution within
18 the temperature range of 298-348 K. The study of the mentioned systems will be able to
19 evaluate the existence possibility of either physical or chemical absorption.

20

21 **2. Experimental Section**

22 ***2.1 Henry's Law Coefficient Measurements***

23 For the determination of Henry's Law Constant and the Infinite Dilution Activity
24 Coefficient, the experimental works were carried out in Mines ParisTech laboratory. The
25 experiment employed the Gas Stripping method using a specially designed apparatus using

1 dilutor and saturator cell. This method is based on the evolution of vapor phase composition
2 when the highly diluted solute of the liquid mixture in an equilibrium cell is stripped from the
3 solution by a flow of inert gas (helium). The composition of the gas leaving the cell is
4 periodically sampled and analyzed using gas chromatography. The peak area of the solute
5 decreases exponentially with the volume of inert gas flowing out from the cell. Detailed
6 descriptions of the principles and experimental apparatus have been discussed previously by
7 Richon et al. [15, 16] and Krummen et al. [12]. Hence, only salient features will be
8 highlighted in the paper.

9

10 **2.2 Chemicals**

11 For this study, the chemicals used are as presented in Table 1. No further purification of
12 the chemicals were made. Ultra pure water was used which was purified and distilled through
13 a Millipore (Direct Q5) osmosis membrane.

14

15 **Table 1.** Chemical sample

16 [INSERT TABLE 1 HERE]

17

18 Water and MDEA were degassed independently. Aqueous MDEA solutions of 25 wt% and
19 50 wt% were prepared under vacuum: respective masses of water and MDEA were
20 determined by differential weighing to prepare a mass fraction (w) of 25 % and 50 % MDEA
21 aqueous solution (mass fraction uncertainty lower than 0.001%).

22

23 **2.3 Equipment**

24 In this gas stripping method, two cells are immersed inside a liquid bath regulated to within
25 0.01 K. A platinum probe, in contact with the liquid phase of the “dilutor cell” connected to

1 an electronic display, is used for temperature readings. Temperature uncertainty of the probe
 2 was estimated; $u(T) = 0.2$ K. Analytical work was carried out using a gas chromatograph
 3 (PERICHROM model PR2100, France) equipped with a flame ionization detector (FID)
 4 connected to a data software system. The reference of the analytical column is: 15%
 5 APIEZON L, 80/100 Mesh (Silcosteel, length 1.2 m, diameter 2 mm) from RESTEK, France.
 6 Helium is used as the carrier gas in this experiment. The simplified flow diagram apparatus is
 7 as per shown in our previous paper [13].

8 In this experiment, a 40 cm^3 of pure solvent was introduced into the “saturator cell (S)” in
 9 upstream section, while about 25 cm^3 of the solute-solvent mixture was introduced into the
 10 “dilutor cell (D)” in the downstream section. A constant stripping gas “helium” flow adjusted
 11 to a given value by means of a mass flow regulator was bubbled through the stirred liquid
 12 phase and stripped the volatile solute into the vapor phase. The gas leaving the dilutor cell
 13 was periodically sampled and analyzed by gas chromatography using a rotating gas sampling
 14 valve [13].

15 Equilibrium must be reached between the gas leaving the cell and the liquid phase in the
 16 cell. This can be checked by verifying the measured activity coefficient value which does not
 17 depend on the eluting gas flow-rate. The peak area of solute decreased exponentially with
 18 time if the analysis is made within the linear range of the detector.

19 The Henry’s Law coefficient, H_i (Pa), of solute i was calculated by means of equation 1
 20 with assumption that the equilibrium has been reached between the gas leaving the cell and
 21 the liquid phase residing inside the cell. Equation 1 is obtained considering mass balance
 22 around the equilibrium cell concerning the solute.

$$23 \quad H_i = -\frac{1}{t} \ln \left(\frac{S_i}{(S_i)_{t=0}} \right) \cdot \frac{RTN}{\frac{D}{P_{soliv}^{sat}} + \frac{V_G}{t} \ln \left(\frac{S_i}{(S_i)_{t=0}} \right)} \quad (1)$$

24

1 where D is the carrier gas flow rate ($\text{m}^3 \cdot \text{s}^{-1}$); N is the total number of moles of solvent inside
 2 the dilutor cell; V_G (m^3) is the volume of the vapor phase inside the dilutor cell; S_i is the
 3 chromatograph solute i peak area; t (s) is the time; T (K) is the temperature inside the cell; P
 4 (101 300 Pa) is the pressure inside the cell (around 1 atm); $P_{\text{solv}}^{\text{sat}}$ (Pa) is the saturation
 5 pressure of the solvent (see Appendix); and R ($\text{J} \cdot \text{mol}^{-1} \cdot \text{K}^{-1}$) is the ideal gas constant.
 6 Uncertainty concerning the Henry's law coefficient is estimated to be within 15 %. This
 7 estimation comes from propagation of errors on the uncertainty of the solute i peak area
 8 determination, the uncertainties on the flow, the uncertainties related to the temperature and
 9 pressure, number of moles of solvent and accuracy of the approach (mass balance and
 10 hypothesis, see Krummen et al. [11]). It can be noticed that the expression given in the paper
 11 of Krummen et al. is wrong but only valid for measurement in non volatile solvent (Eq. 2).

$$12 \quad H_i = -\frac{1}{t} \ln \left(\frac{S_i}{(S_i)_{t=0}} \right) \cdot \frac{RTN}{D \left(1 + \frac{P_{\text{solv}}^{\text{sat}}}{P} \right) + \frac{V_G}{t} \ln \left(\frac{S_i}{(S_i)_{t=0}} \right)} \quad (2)$$

13 with $\frac{1}{1 - \frac{P_{\text{solv}}^{\text{sat}}}{P}} \approx \left(1 + \frac{P_{\text{solv}}^{\text{sat}}}{P} \right)$ for non volatile solvent (saturated pressure is very low, i.e.

14 $\frac{P_{\text{solv}}^{\text{sat}}}{P} \ll 1$. The measurement for this work complied within very low saturated pressure

15 condition where the range of $\frac{P_{\text{solv}}^{\text{sat}}}{P}$ for this work is within 0.03 -0.37).

16 This uncertainty is a consequence of the difficulty determining accurately the slope of the
 17 solute i peak area as a function of time [13]. The slope is determined by linear regression of
 18 area logarithms.

19

20 **3. Experimental Results and Discussion.**

21 **3.1 Henry's Law Constant and Limiting Activity Coefficient in Infinite Dilution**

22 Results tabulated in Tables 2 and 3 show the values of Henry's law constants for the isopropyl
 23 and isobutyl mercaptans in pure water and in aqueous solutions with MDEA concentration of

1 25% and 50% mass fraction of MDEA. In specific, Table 2 shows the data on isopropyl
2 mercaptan whereas Table 3 on isobutyl mercaptan.

3 Figures 1 and 2 show the temperature dependence of the logarithm of the limiting activity
4 coefficient as a function of inverse temperature for n-propyl mercaptan, isopropyl mercaptan
5 n-butyl mercaptan and isobutyl mercaptan, in pure water and in aqueous solutions having
6 similar concentrations as above i.e., mass fraction of 25% and 50% of MDEA. The limiting
7 activity coefficient is calculated through equation 3. Details concerning the calculation of the
8 saturation pressure are presented in the table shown in the Appendix.

$$9 \quad \gamma_i^\infty = \frac{H_i^{P^{sat}}}{P_i^{sat}} \quad (3)$$

10
11 Whilst Figures 5 and 6 show the temperature dependence of the logarithm of the Henry's law
12 constants for isopropyl mercaptan and isobutyl mercaptan in pure water and in the same two
13 MDEA aqueous solutions bearing the same concentrations.

14 The values of the Henry's law constants and limiting activity coefficient for n-propyl
15 mercaptan and n-butyl mercaptan presented in these figures are taken from our previous work
16 [13, 14].

17

15

16 The figures clearly showed that the values of the limiting activity coefficients for isopropyl
17 and isobutyl mercaptans are smaller in MDEA aqueous solutions than in pure water. It can
18 also be observed that the values of the limiting activity coefficient reduces with the increasing
19 concentration of the aqueous amine solutions. The decreasing function of the amine
20 concentration relation is true for all mercaptans considered in the study.

21 Bedell and Miller [17] carried out study on the mercaptans solubility in aqueous amine.
22 The authors concluded that the solubility of mercaptans in amines can be treated as the sum of
23 both a physical solubility and a chemical solubility. For isopropyl and isobutyl mercaptans,
24 the absorption mechanisms observed involved physical and chemical. Due to the addition of
25 MDEA to water, the alkalinity of the solution changes resulting in the increased of mercaptan
26 solubility. It was also observed indirectly that the limiting activity coefficient increases with
27 the solute molecular size (higher number of carbon atoms of mercaptans) at constant MDEA

1 concentration. The reason is due to the physical absorption being the predominant
2 mechanism.

3 The comparison made on the values of the limiting activity coefficients for isobutyl
4 mercaptan and n-butyl mercaptan showed that they were higher for the latter for both amine
5 solutions i.e., concentration of 25 wt% and 50 wt%.

20 ж 50 wt% MDEA-iBM; ● 50 wt% MDEA-nBM)

21

22

23 Figures 3 and 4 present the measured Henry's Law constant as a function of inverse
24 temperature for n-propyl mercaptan, isopropyl mercaptan, n-butyl mercaptan and isobutyl
25 mercaptan species in pure water and in 25 wt % and 50 wt % MDEA aqueous solution
26 respectively. The values for n-propyl mercaptan and n-butyl mercaptan were taken from our
27 previous work [13].

28 It was observed that the the Henry's Law constant for the various species of mercaptans
29 exhibited lower values whilst in the MDEA solution compared to pure water. These effects

1 could be explained through the higher solubility of the mercaptans in the presence of
2 alkanolamine in solutions as a result of higher affinity between the organic molecules namely
3 the mercaptans and the alkanolamine, compared to water. The same deduction was made by
4 Lange et. al [10] in their work on the influence of mercaptans impurities on thermodynamics
5 of amine solutions. Bedell and Miller [17] mentioned in their work that in general the
6 solubilities of higher mercaptans in pure water show a slight decrease in solubility as the
7 mercaptan alkyl groups increase in size. Results obtained in this work are in fair agreement
8 with their statement as higher mercaptans exhibited higher values of Henry's Law constant (as
9 shown in Table 1 and 2). Higher Henry's Law constant values translate to lower solubilities of
10 a gas in a solvent and vice versa.

11 Another important observation that could be made from Figure 3 is the higher Henry's
12 Law constant exhibited by the isopropyl mercaptan compared to the n-propyl mercaptan
13 which were consistent for both MDEA solutions i.e., 25 wt % and 50 wt % concentrations.
14 The same observation was also made for the isobutyl and n-butyl mercaptans at 25 wt % and
15 50 wt % of amine concentration as shown in Figure 4. The Henry's Law constant for the
16 former was also found to be higher. The significance of the result above is that the Henry's
17 Law constant increases with the solute molecular size. Density of the two pairs showed that
18 the n-propyl and the n-butyl display higher values compared to the iso-propyl and iso-buytl
19 mercaptan as shown in Table 4. The higher density of n-butyl and n-propyl mercaptan species
20 tend to have more compact molecular arrangement hence leading to smaller molecular size
21 could fit more easily in the solvent cavity. These findings agree with the works by
22 Tsonopoulos [18].

23

24 **Table 4.** Density of Isopropyl Mercaptan, n-propyl Mercaptan, Isobutyl Mercaptan and n-
25 butyl Mercaptan at atm, 25°C [19]

1 [INSERT TABLE 4 HERE]

2

3 The argument could also be further supported through the determination of the Hildebrand

4 solubility parameter of the mercaptan species involved in the study as shown in Table 5.

5 Theoretically, the solubility parameter is a numerical value that indicates the relative solvency

6 behaviour of a specific solvent and it is derived from the square root of the cohesive energy

7 density of the solvent [20]. Hildebrand solubility parameters obtained from literature [21] are

8 calculated through equation 4.

9
$$\delta = \sqrt{c} = \left[\frac{\Delta H - RT}{V_m} \right]^{1/2} \quad (4)$$

10 where c is the cohesive energy density ; ΔH is heat of vaporization($\text{kJ}\cdot\text{mol}^{-1}$), V_m is molar

11 volume of the mixture ($\text{m}^3\cdot\text{mol}^{-1}$); T is the temperature (K) and R is the ideal gas constant

12 ($\text{J}\cdot\text{mol}^{-1}\cdot\text{K}^{-1}$). By ranking solvents according to Hildebrand solubility parameter a solvent

13 range is obtained, with solvents occupying positions in proximity to other solvents of

14 comparable strength [19].

15

16 **Table 5.** Hildebrand Solubility parameter of Isopropyl Mercaptan, n-propyl Mercaptan,

17 Isobutyl Mercaptan and n-butyl Mercaptan [21]

18 [INSERT TABLE 5 HERE]

19

20 Figures 5 shows the plotted values of the Henry's Law Constant and the limiting activity

21 coefficient of the isobutyl mercaptan in water and in the various MDEA solution

22 concentrations at different temperature (298-348 K). The figures are tendency curves that are

23 useful for quick estimation of solubility and limiting activity coefficient value for the isobutyl

24 mercaptan under different MDEA solution concentrations i.e., within the range of 0 - 15 mole

1 fraction (similarly to 0 - 50 wt %). Similar tendency curves can also be plotted for all the
2 mercaptan species in this work.

3

4 [INSERT FIGURE 5 HERE]

5

7 water and in various MDEA weight fractions at different temperature ◆ 298K ■ 323K
8 ▲ 333K × 348K.

9

10 3.2 Heat of Solutions

11 To evaluate the effect of different concentration, the heat of solution is determined through
12 equation 5. The equation is derived from the Gibbs-Helmholtz equation using excess
13 thermodynamic properties.

$$14 \left(\frac{\partial \ln H_i}{\partial 1/T} \right)_P = \frac{\Delta H_i}{R} \quad (5)$$

15 The heat of solution (ΔH_i (J.mol⁻¹)) is also considered to be the partial molar excess
16 enthalpy of component *i* in the solution. By assuming that the heat of solution is a constant
17 and by integrating equation 6, it can be shown that limiting activity coefficient can be
18 expressed as a function of 1/T.

$$19 \ln H_i = A + \frac{B}{T} \quad (6)$$

20 Which resulted in $\Delta H_i = RB$. Table 6 reported the results of the heat of solutions at
21 different MDEA solution concentrations for isopropyl and isobutyl mercaptans.

[INSERT FIGURE 6 HERE]

Figure 6. n-propyl, iso-propyl, n-butyl and iso-butyl mercaptans heats of solution as a function of MDEA molar concentration. (× nPM; ■ iPM; ▲ nBM; ◆ iBM)

Figure 6 shows the heats of solution for, n-propyl, isopropyl, n-butyl and isobutyl mercaptans as a function of MDEA concentration in mole fraction. From Table 6 and Figure 6, it can be observed that the heat of solution for n-compounds are higher than the iso-compounds for both propyl and butyl mercaptans at all different concentrations of MDEA solutions.

Also, it is known that the heat of solution are contributed by three effects namely a positive heat of cavitation, a negative heat of hydrophobic interactions, and the heat of reaction (here between acids R-SH and base (amines or water)) [16]. When MDEA is added in the aqueous solution, it is probable that the contribution of chemical reactions are increased as there is a change in the value of heat of solution. Another way to explain: the heat of solution is the sum of the contribution of breaking solute solute and solvent solvent interactions and creation of solvent solute interaction. Acid base reactions are also exothermic. The two first are endothermic and the last one is exothermic. According to Table 6 the final results show that more energy is releasing during the solvation probably due to acid base reaction.

Moreover, in pure water, the difference in the heat of solution is due to the size effect (physical solubility) causing the partial molar excess enthalpy to be slightly higher for the iso-compound. In addition, with higher value of Henry's Law Constant shown by isobutyl and isopropyl mercaptan, indicates that the solute are less soluble in the alkanolamine solution thus less energy required to remove the solute from the solution. It is also observed that heat

1 of solution for isopropyl and isobutyl mercaptans have the same order of magnitude and the
2 same shape.

3 As for the both iso and n-propyl and butyl mercaptan, the n-butyl and isobutyl mercaptan
4 shows a higher heat of solution values due to the presence of an additional alkyl group
5 compared to the n-propyl and isopropyl mercaptan.

6

7 **4. Conclusion**

8 The new values for Henry's Law constants and the infinite dilution activity coefficients of
9 n-propyl mercaptan, isopropyl mercaptan n-butyl mercaptan, isobutyl mercaptan in 25 wt %
10 and 50 wt % MDEA aqueous solution at $T = (298 \text{ to } 348 \text{ K})$ have been obtained through gas
11 stripping measurements. Based on general observation, it can be concluded that that the
12 limiting activity coefficient and Henry's Law constant is an increasing function of the solute
13 molecular size value. The observation can be supported through the determination of
14 Hildebrand solubility parameter for the components and solvent involved. The experimental
15 technique has provided information about heats of solution of MDEA aqueous solution.

16

17 **5. Acknowledgment**

18 The authors wish to thanks Dr. Stanley Huang from Chevron Energy Technology Corporation
19 and member of Gas Processor Association research Committee for fruitful discussion and
20 advice.

21

1
2 **Appendix**

3 Correlation used to calculate vapor pressure is

4
$$P^{sat} = e^{\left(A + \frac{B}{T} + C \ln(T) + D \cdot T^E\right)}$$

5 with the following parameters (Table 7) ;

6 Concerning the solvent, the expression is

7
$$P_{solv}^{sat} = x_{water} P_{water}^{sat} + x_{MDEA} P_{MDEA}^{sat}$$

8

9 **Table 7:** Vapor pressure correlation parameters.

10 [INSERT TABLE 7 HERE]

11

12 These parameters (for the mercaptans) were obtained after adjustment on literature data (from

13 ThermoDataEngine version 3.0 from NIST) by minimising the objective function,

14
$$F = \sum (P_{exp} - P_{cal})^2$$

15 The AAD (average absolute deviations) are presented in the following Table 8:

16

17 **Table 8:** Average absolute deviations (AAD) values .
